

progRESsHEAT

Comparing different district heating supply scenarios with energy savings and individual supply options in six European municipalities

Marie Münster, Sara Ben Amer-Allam, Stefan Petrovic, Daniel Møller Sneum, DTU

of the European Union

Outline

- progRESsHEAT project
- Least Cost Tool
- Case presentations and preliminary results
- Conclusions
- Key success factors

progRESsHEAT

Core objective

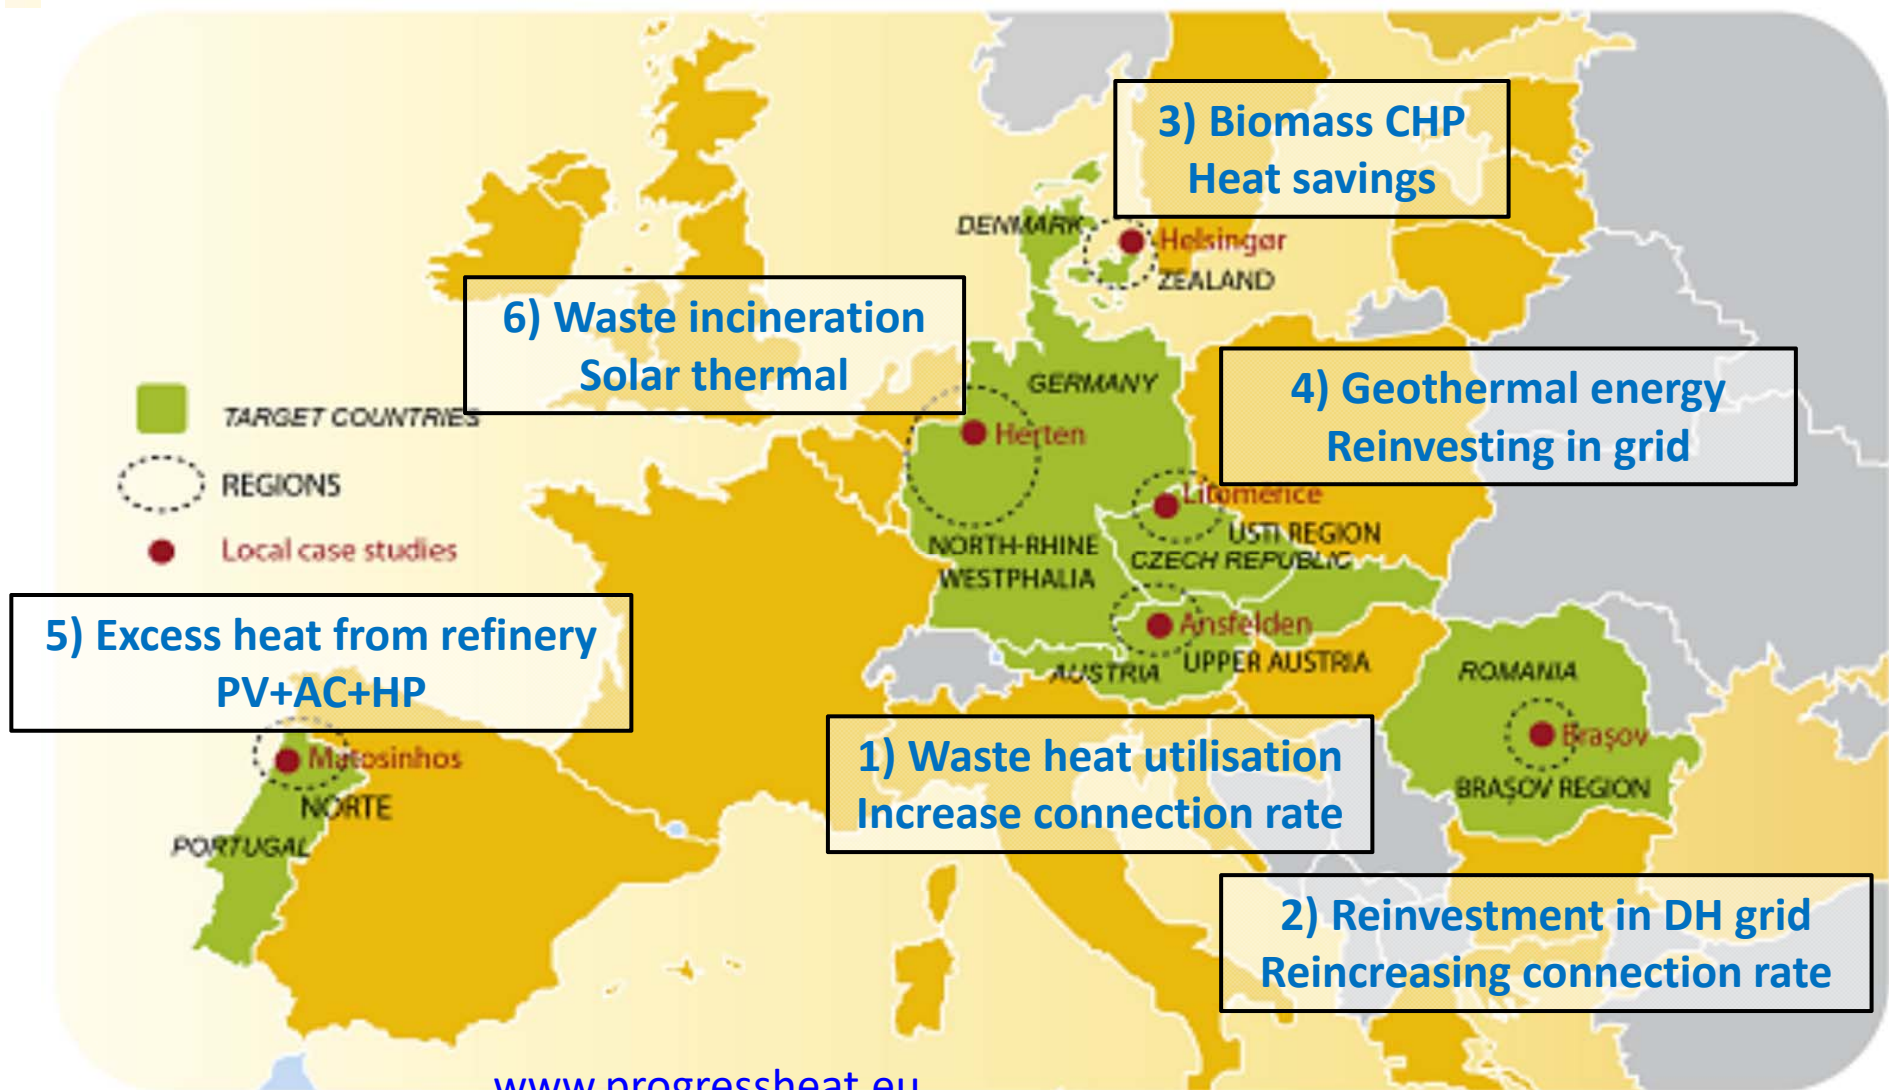

Support **policy makers** and **public authorities** at **local, regional and national level** in the development and implementation of **integrated strategies** and **policies** to enforce the use of **renewable and efficient heating and cooling solutions** in their regions

- **6 Countries:** Denmark, Germany, Czech Republic, Austria, Portugal and Romania
- **3 Geographical levels:** National, regional and municipal
- **Project duration:** March 2015 – October 2017
- **Project partners:** Scientific partners, Communication partners, Local partners

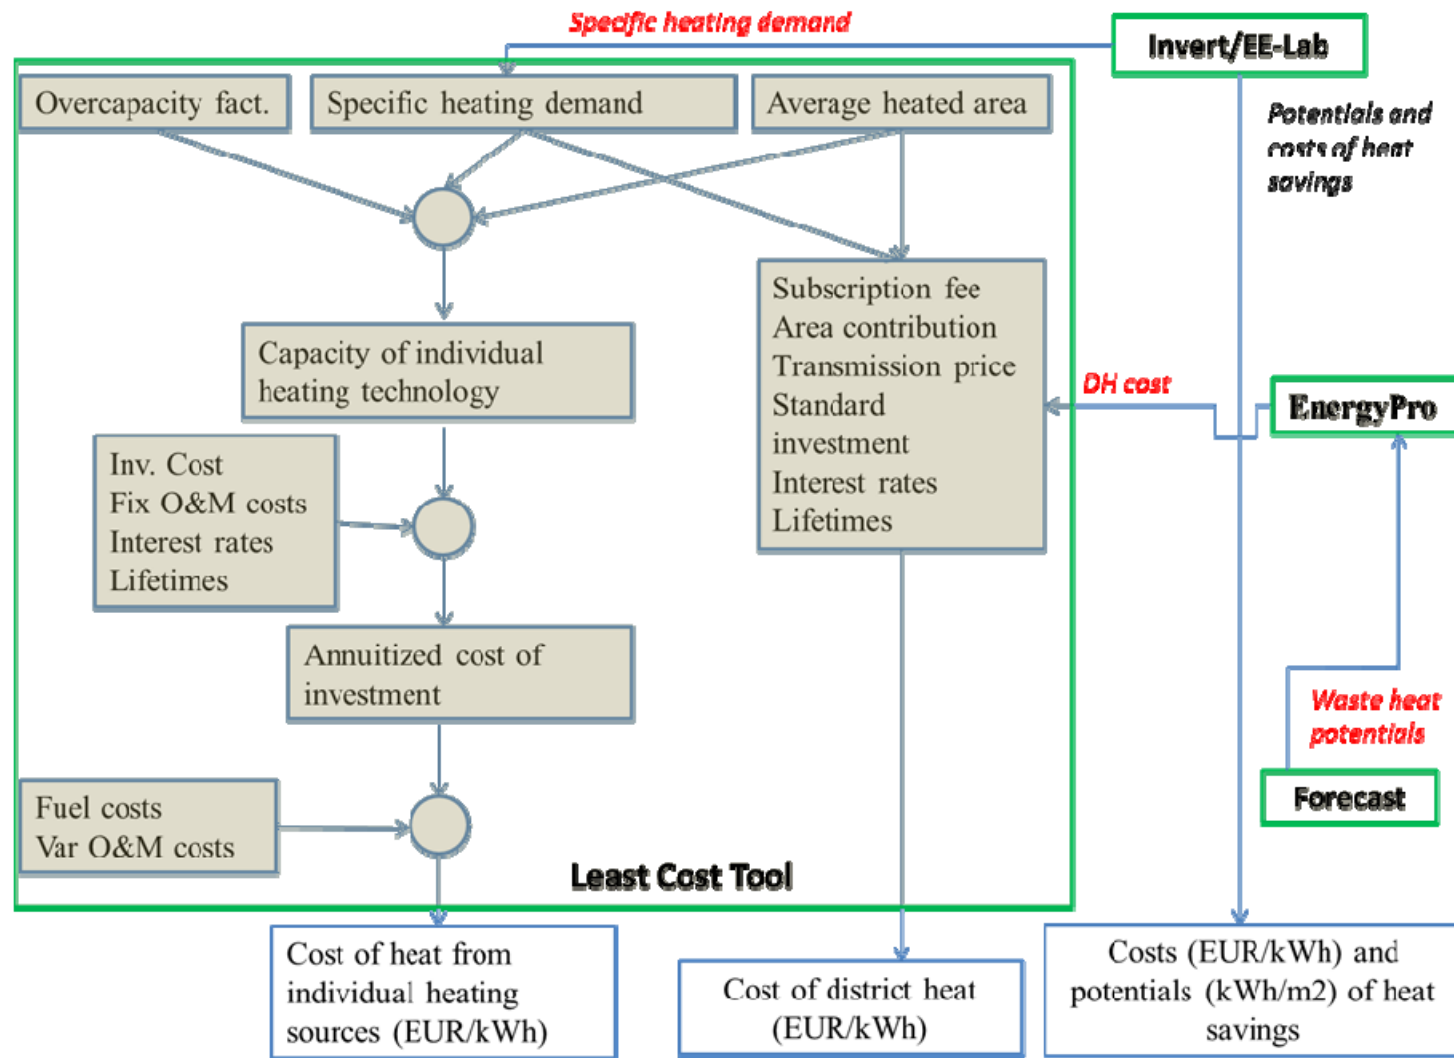

Comparing different district heating supply scenarios

Local cases

Least Cost Tool – part 1

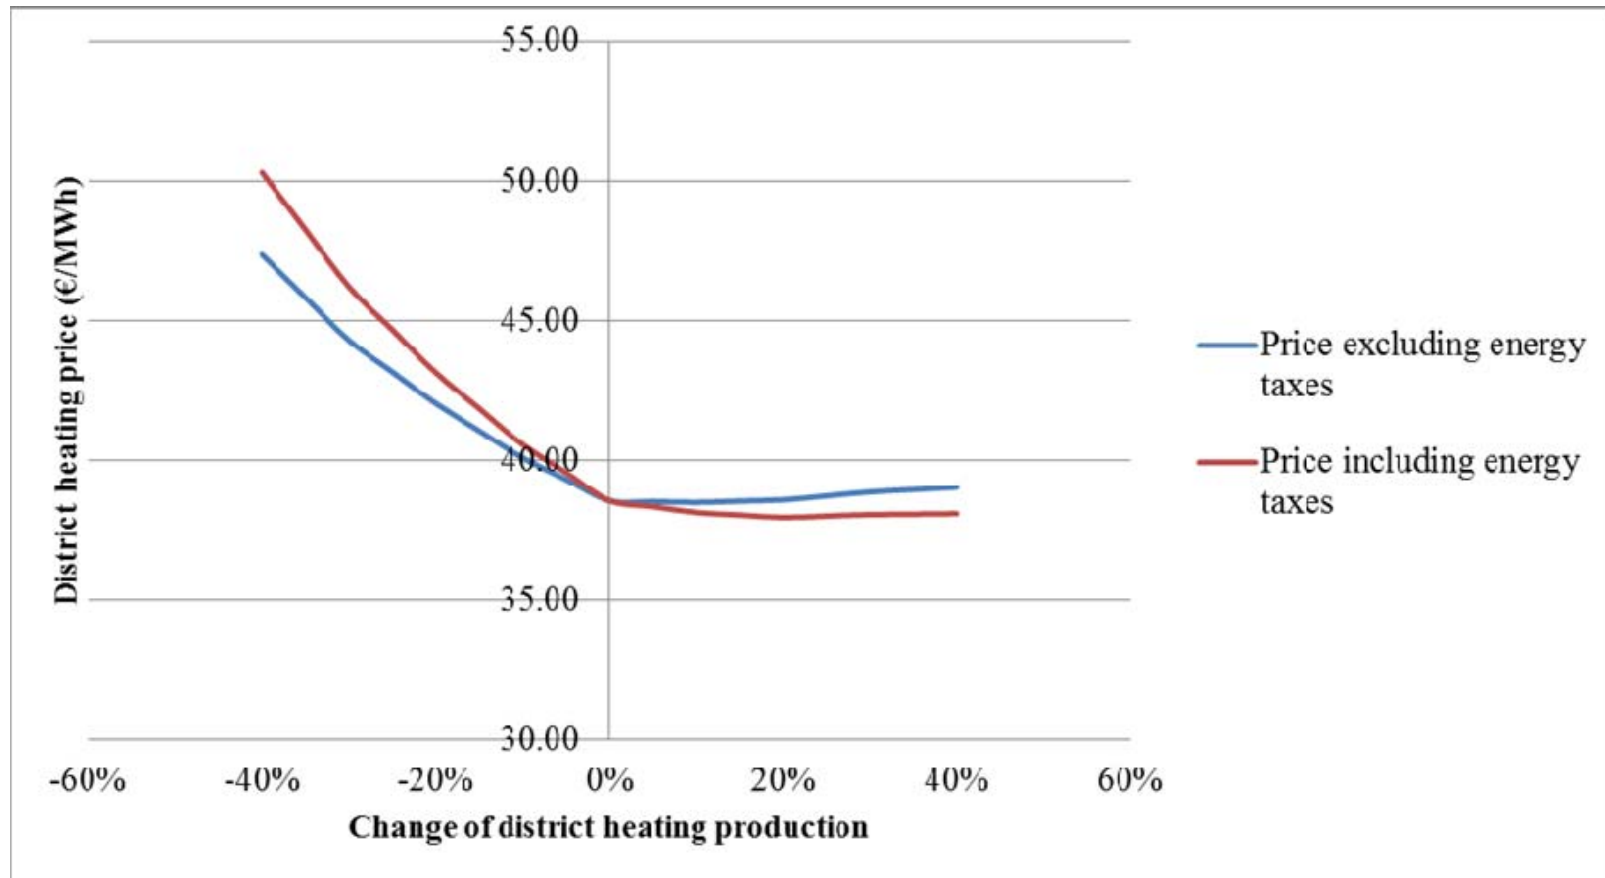

Comparing different district heating supply scenarios

Least Cost Tool

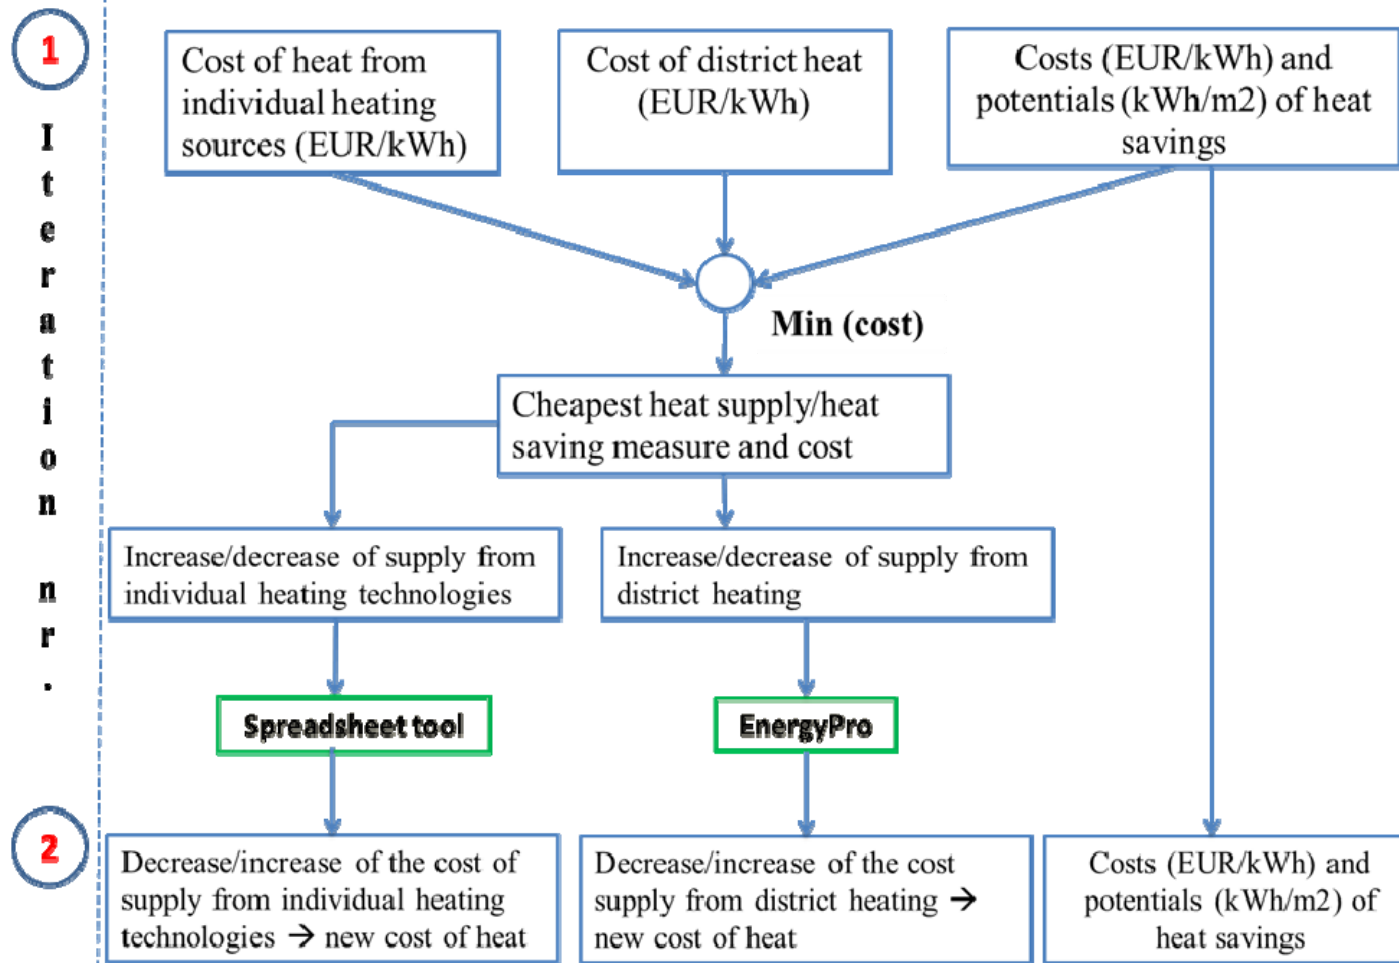

input from EnergyPro

Comparing different district heating supply scenarios

Least Cost Tool – part 2

Comparing different district heating supply scenarios

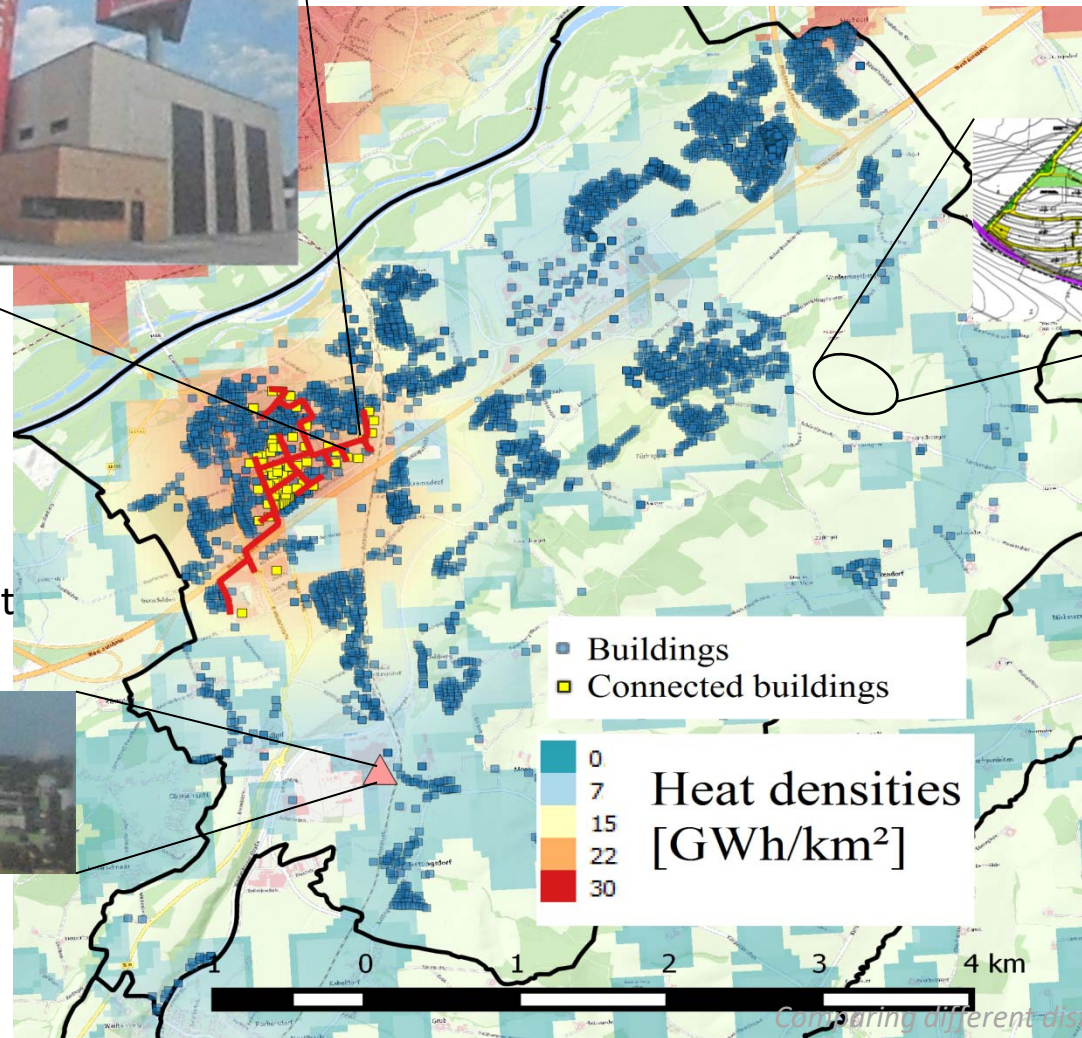

Case Ansfelden

Current biomass district heating network

Industrial site with waste-heat potential

New development area

Comparing different district heating supply scenarios

Case Ansfelden - Feasible initiatives

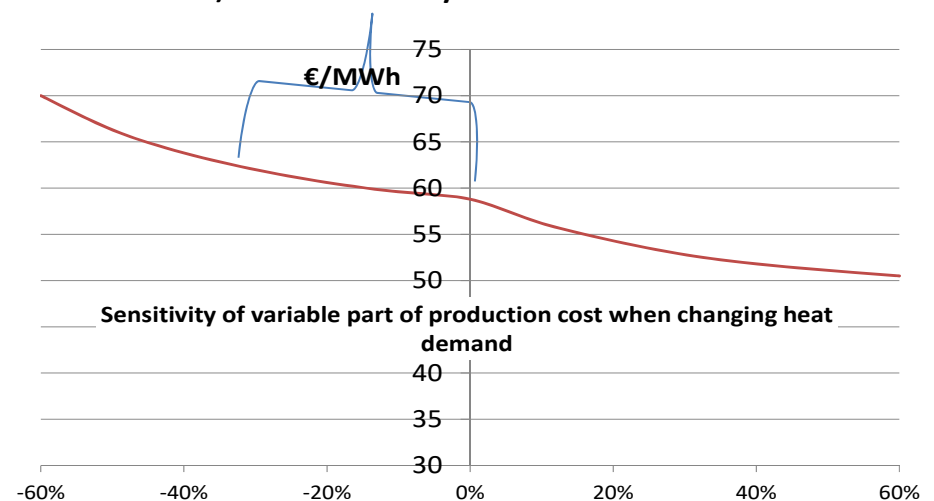

Decreasing heat demand may lead to increasing heat prices for DH:

- Example: old (1945-1980), small (around 500m²) multi-family-houses

1. Heat saving is cheapest option: -34% in demand

2. DH supply costs (variable and fixed costs) increase by 22%

3. Heat supply cost from individual biomass boilers stays constant

4. Cheapest combination: heat savings and individual biomass boilers

Additional analyses to be carried out including other heat generation options and settings

Comparing different district heating supply scenarios

Case Ansfelden - Key success factor

- Solution: waste heat utilisation?
 - Interest from paper industry?
 - Owner/ risk taker?
- Increase connection rate
 - Subsidies for biomass DH
 - And for connecting to DH?
- Climate goal for new local settlement

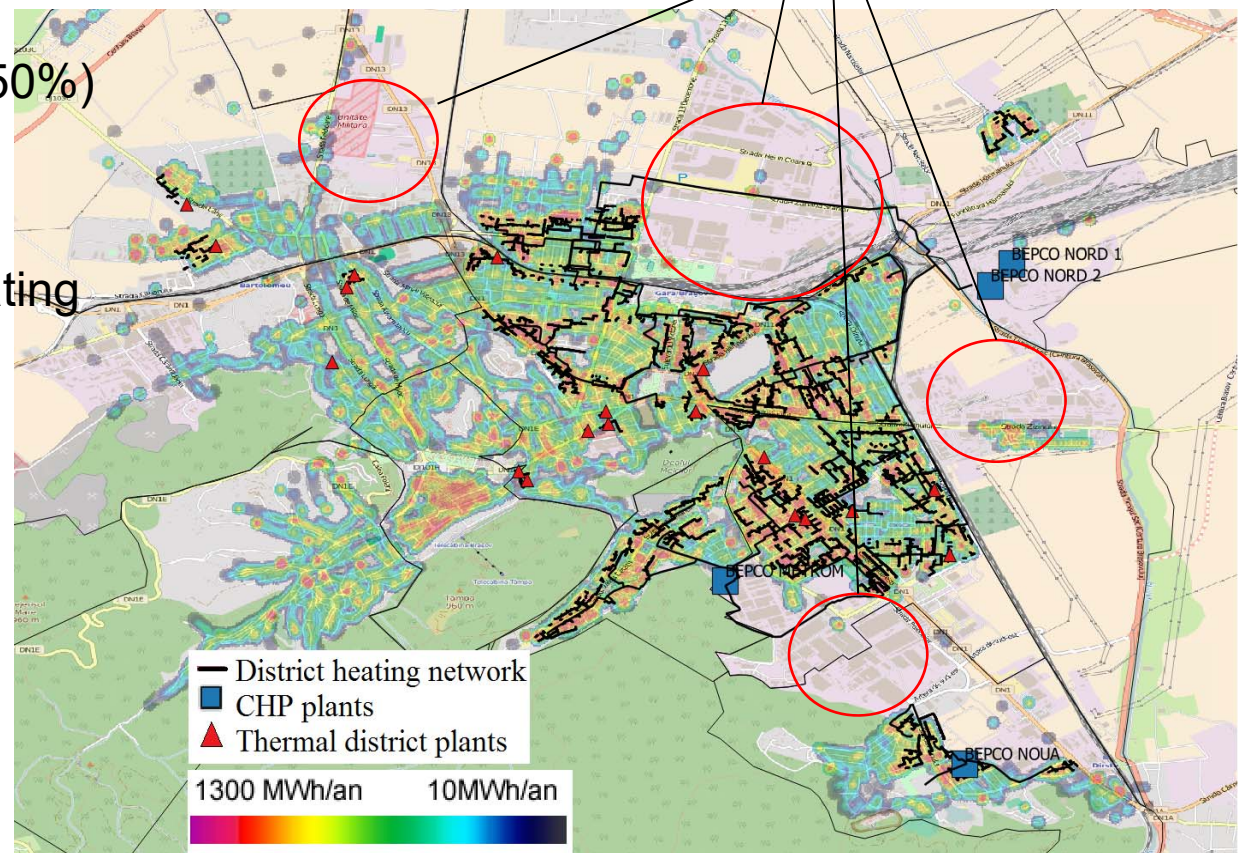

Case Brasov - Setting the scene

- Old district heating system formerly supplying industry and households
- Industry closed down 1990
- Now overdimensioned and unreliable
- Big losses in network (>50%)
- Split ownership of grid and heat generation
- Bad image of district heating
- Change to individual gas boiler

Former industrial sites
Changing to commerce or
settlement area

Share of heat supply options in Brasov

Case Brasov - Feasible initiatives

Scenario of renewing the network until 2030

- Estimated additional investments of 55 Mio €
 - Drop of losses from >50% to 10%
 - Assumption that saved heat can be sold to additional costumers
- increase of DH price of only +12%

Scenario of renewing the network until 2030 and use whole capacity of supply units to connect additional costumers

→ decrease of DH price by -22%

Case Brasov - Key success factor

- New settlement with mandatory connection to DH
- Municipal ownership of DH grid?
 - Long-term investment horizon of a strategic investor is required (e.g. the municipality)
- Clear and stable contracts with heat suppliers (if different from grid owner)
- New image for DH

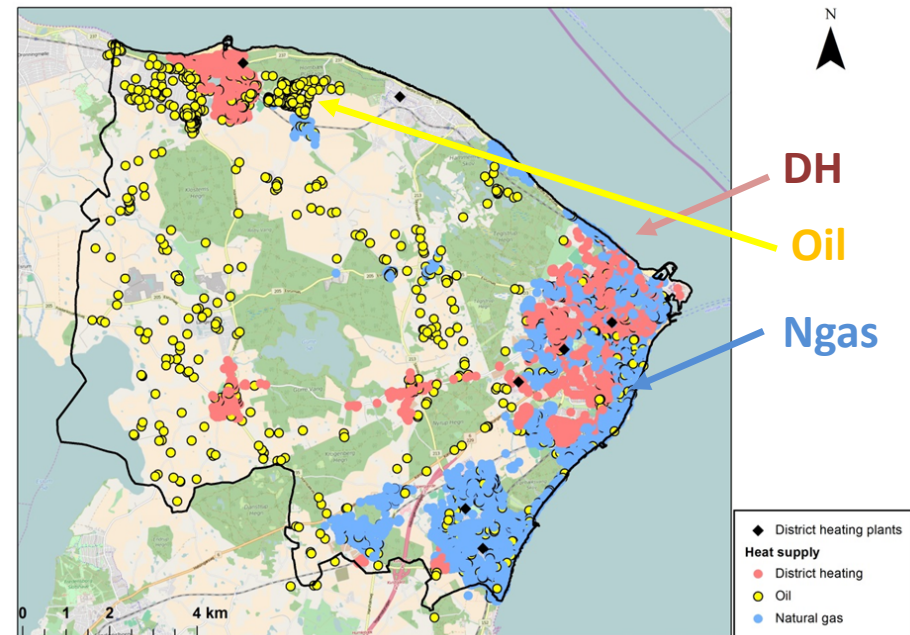

Municipality of Helsingør

- Northeastern part of the Zealand island, Denmark
- 122 km²
- 62.000 inhabitants in 2013
- Total CO₂ emissions: 5.6 tCO₂ eq. per cap.

- DH based on natural gas CHP and waste incineration

Heat supply types in 2013

Helsingør - Feasible initiatives

Scenarios

- BAU: biomass CHP being built
- RES (no fuel oil or ngas boilers)
- HP (heatpumps and heat storage)

Perspectives

- A - Simple socio-economic
- B - Private economic (incl tax)

Share of district heating, 2030

■ DH areas ■ Next-to-DH areas ■ Total Helsingør

Share of heat savings, 2030

Biomass CHP + DH expansion is private economically feasible (from 35 to 53%) (no tax on biomass)

30-40% heat savings are private economically feasible; mainly

- in old buildings
- outside DH areas

Comparing different district heating supply scenarios

Helsingør

Key success factors

- Zero tax on biomass - and subsidy for CHPs that generate electricity using biomass
- Heat supply zoning - and proving that DH is more socio-economically feasible
- Loans with 1.5% interest rate guaranteed by the municipality
- Non-profit rule for DH companies
- Thermal renovations happen together with other renovations

Municipality of Litoměřice

Location Northern part of the Czech Republic

Area 1 340 km²

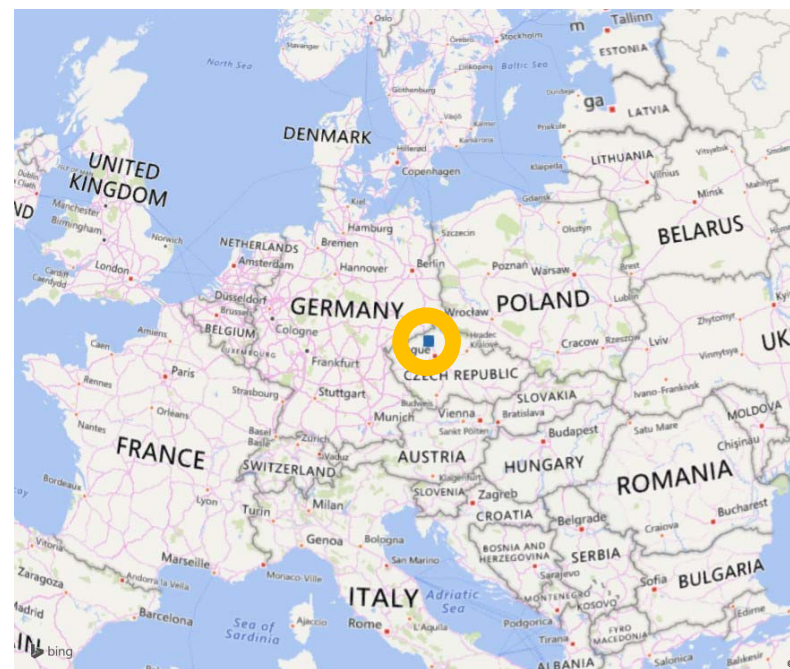

Inhabitants 24.000 in 2013

CO₂ 136 ktCO₂ eq. (2013). 5.7 tCO₂ eq. per cap.

Heat demand used in model

- Litomerice DH
- Litomerice Natural gas
- Litomerice Biomass

Comparing different district heating supply scenarios

Litoměřice

Feasible initiatives

Scenarios

- BAU
- Exp - DH expansion
- Exp Geo - DH expansion and geothermal CHP plant

Comparing different district heating supply scenarios

Litoměřice

Key success factors

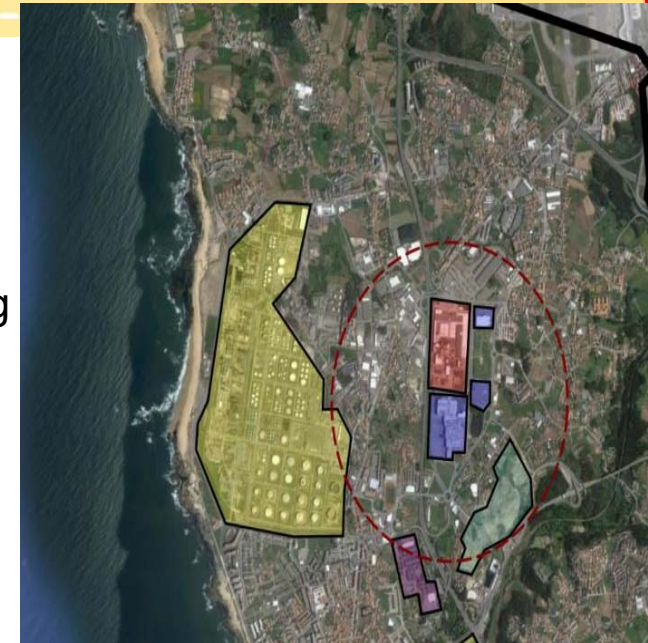

- Ownership of DH plant - or clear terms of access to the DH grid
- New image of DH: Consumers need to see key numbers on cost and other relevant inputs (such as CO₂/MWh or jobs/year)
- Cost savings possible through conversion to DH with construction of geothermal plant.
- Risk management related to exploring geothermal energy

Matosinhos

- **Focus area:**
 - Shopping mall and large stores
 - Individual gas boilers + compression chillers
 - Demand for cooling three times higher than heating
 - Residential area under construction
 - Refinery as potential excess heat source
 - No DHC infrastructure in the city and surroundings
- **Energy demand in focus area:**
 - Cooling: 28 GWh/a (at right bottom in blue)
 - Heating: 15 GWh/a
- **Scenario analysis focuses on:**
 - Role of solar thermal, PV and HP
 - Economic viability of DHC
 - Connection of refinery for excess heat use
- **Simple socio-economic perspective:**
 - 1.5% discount rate, no taxes, no externalities

Matosinhos - Feasible initiatives: Results for LCOH and CO₂

Comparing different district heating supply scenarios

Matosinhos

Key success factors

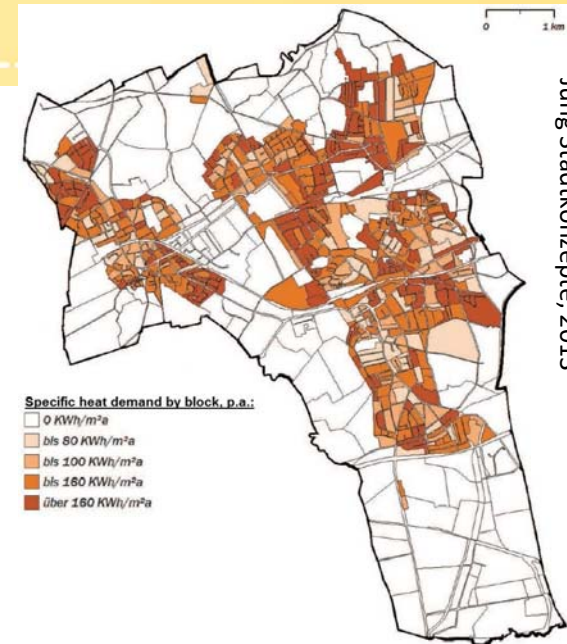

- Using **excess heat from refinery** seems very promising
 - close to city and not yet used
 - Estimated sufficient to supply focus area
 - Can be an opportunity to establish DH grid („door opener“)
 - However:
 - No tradition/ experience with DH in Portugal (only one network in Lisbon)
 - Uncertainty about future perspective of refinery
- **Photovoltaic** can be an option to decarbonize heating & cooling based on decentral **heat pumps** and **compression chillers**
 - High share of cooling -> el demand equally distributed across year
 - Building roofs (plus parking roofs) provide enough space
 - Current estimates with annual net metering (-> explore real time self consumption)
 - Attractive tariffs for HP and PV crucial

Herten

- 2 divided DH grids:
 - North: fed by coal CHP from transmission grid
 - South: fed by waste incineration
- Several distribution networks individually connected to DH transmission line
- Simple socio-economic perspective:
 - 1.5% discount rate, no taxes, no externalities

2 DH scenarios:

1. Constant connection
2. Extending connection so that total heat demand remains relatively constant (see right)

Scenario 2: DH share by building type

Building type	2014	2030	2050
Detached house	14%	14%	14%
Terraced house	25%	25%	91%
Apartment building	40%	59%	100%
Large apartment building	55%	100%	100%

Herten - Feasible solutions: Solar thermal DH

Cost assumptions

	Costs
Land	5,30 EUR/m ²
Collector field	200 to 400 EUR/m ²
Pit Storage	50 to 200 EUR/m ³

Example sub-system „Innenstadt“ (right)

- Across all sizes: LCOH range from 20-30 euros/MWh
- Solar fraction of ~20% can be achieved at ~20 euros/MWh LCOH
- < 4,000 m²: systems without thermal storage have lowest LCOH
- 4 – 25,000 m²: systems with 2,000 m³ thermal storage have lowest LCOH
- Sufficient agricultural land is available

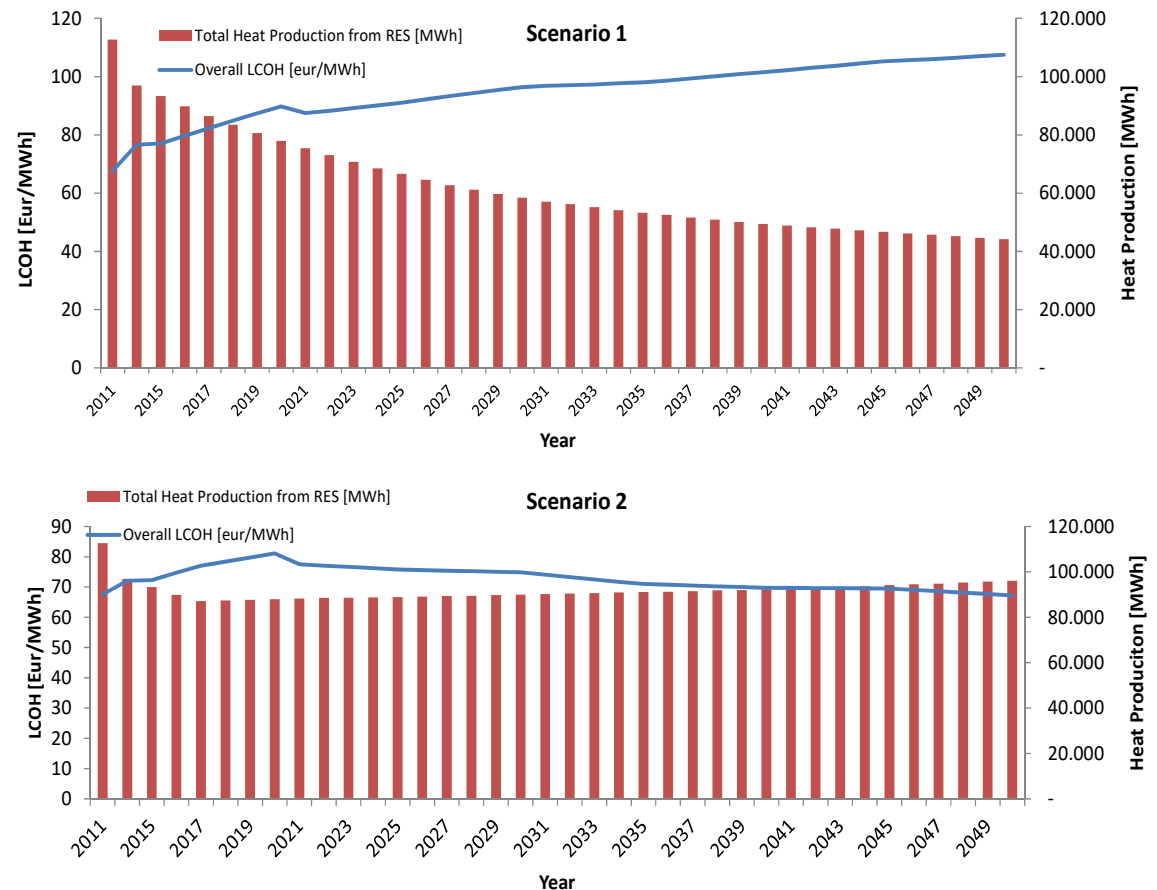

Comparing different district heating supply scenarios

Herten - Key success factors: extension of DH

- LCOH increase with falling heat demand (top)
- LCOH slightly fall with constant heat demand (bottom)
- Connecting new buildings can keep heat demand on constant level up until 2050 at least
- Assumptions
 - No reinvestment
 - Increasing prices

Comparing different district heating supply scenarios

Conclusions

Energy efficient heating and cooling consists of:

- Energy savings
- Individual and central green energy
- Efficient district energy

Efficient green district energy solutions are cheapest for society - when ensuring high connection rate

- should also be cheapest for individuals

Interesting DH supply options are:

- Excess heat
- Waste-to-Energy
- Solar heat
- Heat pumps
- Sustainable biomass

Energy savings and individual green energy should be made easily available for the rest

Conclusion:

Key success factors (I)

Strategic local and regional heat/cool planning

- Long term environmental political targets (both at local and national level)
- Info campaigns and cooperation to smoothen transition
- Better geographic data availability (buildings, waste heat potentials, cooling demands and local RE resources)
- Availability, time and competences to use DH/C planning tools at local level (part of progRESsHEAT)

Conclusion: Key success factors (II)

Regulation

- Zoning to avoid double infrastructure (of respectively DH and natural gas) (mandatory connection in DH priority areas?)
- Ownership structures (including equal access to grids)
- Mandatory improvements of energy efficiency in buildings and industry? Including:
 1. energy savings
 2. efficiency improvements in DHC grids
 3. individual or DHC RE use
 4. DHC expansion

Conclusion: Key success factors (III)

Economy

- Access to cheap long term financing or subsidies (also for upgrading existing grids or investing in new)
- Risk taking - in particular in relation to industries
- Increased heat savings in DH areas must be matched by increased DH connection rate (or DH prices will increase)
- Non profit DH/C? (as in Denmark)
- Aligned taxes, tariffs and subsidies (CO2, fuels, electricity for HP and use of waste heat)

**Thank you for your
attention!**
